Fly Killer Instructions

The Fly Killer Parasites will be shipped to you in a bag with wood shavings. Depending on temperatures, they will begin to hatch within 2-5 days after arrival. When you start to see them moving around inside the bag, it is time to release.

For best results: scratch about 1/2 inch hole in several areas. Choose fly breeding spots such as manure piles, and garbage collection areas. Place some of the Fly Killer Parasites in the hole, and lightly cover with dirt or manure. They will move around in a 100 yard radius in search of fly pupae.

Use of fly baits, or traps can help with the existing adult fly population, Be careful with spray chemicals, as they will kill these fly predators as well. Flies can also develop chemical resistance to sprays.
